

## **Groundwater Model Status: In Progress**

The current model being developed is a 28-layer model that simulates changes in water levels, streamflows, and the position and movement of the freshwater/saltwater interface in response to changes in pumping and recharge from 1900 – 2019, and for a number of what-if scenarios developed by the NYSDEC and in conjunction with the project Steering Committee. This model will be completed and the report that documents the model development and water-resources analyses will be published by December 2022.
